Psychometric Properties of Psychophysiological Paradigms in the NIMH RDoC: Startle and Corrugator Response in NPU, Affective Picture Viewing, and Resting State Tasks Jesse T. Kaye, Daniel E. Bradford, & John J. Curtin **Department of Psychology, University of Wisconsin – Madison**

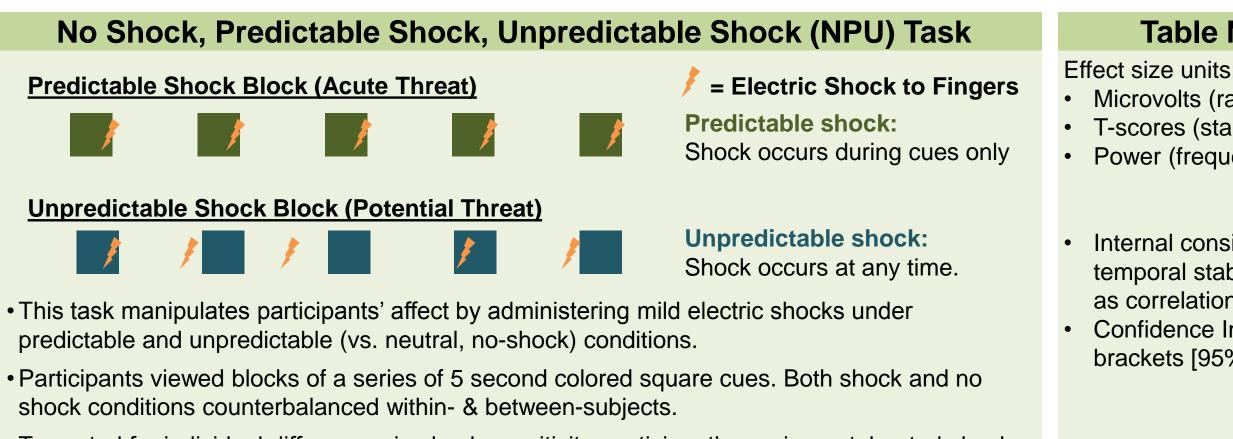

Study Objectives

Psychophysiology tasks are poised to become a major contributor to the National Institute of Mental Health Research Domains Criteria (RDoC) and related experimental medicine initiatives. For these tasks to meaningfully contribute to the RDoC they must possess sound psychometric properties.

We designed the current study to comprehensively evaluate key psychometric properties of startle and corrugator response modulation in three commonly used psychophysiology tasks that can be anchored within the RDoC Negative Valence System domain.

1) Effect size and stability: We examine the strength and stability of each focal task manipulation (e.g., unpredictable shock vs. no-shock in NPU Task, unpleasant vs. neutral pictures) by quantifying its effect size and testing for an effect of study visit (visit 1 vs. 2). 2) Internal consistency: We examine split-half reliability using Spearman-Brown corrected Pearson correlations between odd and even trials to quantify internal consistency within subjects.

3) Temporal stability: We examine temporal stability using Pearson correlations between study visit 1 and study visit 2 to quantify the stability of individual differences in responses over one week.

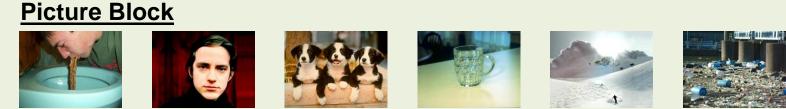

- To control for individual differences in shock sensitivity, participant's maximum tolerated shock at 1st study visit is used during the NPU Task at both visits.
- Startle potentiation = shock cues minus no shock cues (not displayed)

Affective Picture Viewing Task

- This task manipulates participants' affect by presenting unpleasant, pleasant, and neutral pictures from the International Affective Picture System (IAPS).
- Participants viewed 36 different pictures (set) at each study visit comprising 12 pleasant, 12 unpleasant and 12 neutral pictures. Pictures were displayed for 6s each in blocks.
- Picture condition order was counterbalanced within- & between-subjects and picture set order was counter balanced between-subjects.
- **Pleasant startle modulation** = pleasant minus neutral pictures
- **Unpleasant startle modulation** = unpleasant minus neutral pictures

Resting State Task

- This task involves a period of time characterized by the absence of other explicit manipulations or potent experimental stimuli, often conducted at "baseline".
- General startle reactivity during this task has been suggested to index individual differences in defensive reactivity within the Negative Valence System domain of the RDoC.
- Participants viewed a fixation cross while 9 startle probes were presented at random intervals. No other distracting stimuli were presented (e.g., images or shock).
- General startle reactivity was calculated as the mean raw startle response during the Resting State Task.

Effect S Gener

Internal Gener

Tempora Gener

- - Significant effect (p < .05) of:
 - * Effect size or correlation (non-zero)
 - ^a Study visit for raw startle

^b Study visit for startle standardized scores or for corrugator power in frequency domain

^c Difference in psychometric property (i.e., internal consistency or temporal stability) between quantification methods within each measure.

- Healthy participants (N=128, 64 female) completed three psychophy visits separated by one week.
- Participants first completed the Resting State Task and were then ra task: NPU Task or Affective Picture Viewing Task) for both study visit
- The startle and corrugator responses are measures of negative affect modulated by emotional stimuli (e.g. potentiated by threat)
- EMG sensors over the orbicularis occuli and corrugator supercilii muscles measure activity associated with the eyeblink and frown, respectively. Responses are measured during shock cues in the NPU Task or pictures in the Affective Picture Viewing Task to acoustic probes for startle and cue/picture-onset for corrugator.

	Unpredictable Potentiation ^c	.71 [.60, .79]*	.49 [.33, .62]*	

NPU Task startle potentiation displayed large effect sizes across study visits and good internal consistency and temporal stability, making it a robust and reliable task-measure pairing.

Affective Picture Viewing Task: Startle Modulation					
	Raw Scores		Standardized Scores		
Effect Size & Stability	Visit 1	Visit 2	Visit 1	Visit 2	
Pleasant Modulation ^b	-4.7 [-6.4, -3.0]*	-1.9 [-4.3, 0.5]	-1.5 [-2.4, -0.7]*	-0.1 [-1.0, 0.7]

Pleasant Modulation ^c	.16 [21, .41]		10 [38, .23]		
Unpleasant Modulation	.07 [34, .35]		.14 [25, .41]		
Temporal Stability	Visit 1 to Visit 2		Visit 1 to Visit 2		
Pleasant Modulation	-0.1[19, .18]		.08 [10, .26]		
Unpleasant Modulation	.50 [.35, .63]*		.40 [.24, .54]*		

Unpleasant pictures produced large startle modulation, adequate temporal stability, but poor internal consistency. Psychometric properties of pleasant pictures startle modulation were poor.
